PROJECT DOCUMENTATION

AUTO TICKET CLASSIFICATION USING FLOW DESIGNER

1. PROJECT DETAILS

Project Title	AUTO TICKET CLASSIFICATION USING FLOW DESIGNER
Platform	ServiceNow
Team ID	SWTID-2026-6960
Team Leader	S. Subha
Leader Mail ID	sbhswathi@gmail.com
Team Members	R. Kowsalya - kowsi07kowsalya@gmailR. Kowsalya - kowsalyarangaraj9@gmail.comM. Sujatha - sujathayuvaraj07@gmail.comC. Pavithra - pavithra86100@gmail.com

2. ABSTRACT

The Auto Ticket Classification using Flow Designer project automates the classification of ServiceNow incident tickets. When an incident is created, the flow reads the ticket information, especially the short description and description, and applies predefined classification rules. Based on the identified issue, the flow automatically updates fields such as Category and Subcategory. This reduces manual classification effort, improves consistency, and helps support teams route and manage incidents more efficiently.

3. INTRODUCTION

ServiceNow is an enterprise platform used to manage incidents, requests, and other IT

service operations. In a manual incident-management process, support agents often need to read each ticket and decide its appropriate category and subcategory. Auto Ticket Classification uses ServiceNow Flow Designer to automate this repetitive task. The flow evaluates ticket information and assigns the appropriate classification according to predefined business rules.

4. PROBLEM STATEMENT

Manual ticket classification can take additional time and may lead to inconsistent categorization. Different agents may classify similar incidents differently, making reporting, routing, and analysis more difficult. A simple and maintainable automation is required to classify newly created incident tickets automatically based on their issue description.

5. OBJECTIVES

Automatically classify newly created incident tickets.

Use Flow Designer to evaluate ticket descriptions and related information.

Automatically update Category and Subcategory fields.

Reduce manual effort for service-desk agents.

Improve consistency in incident classification.

Provide a simple and maintainable automation workflow.

6. EXISTING SYSTEMS

The existing approach mainly depends on manual ticket classification. After an incident is created, a service-desk agent reads the ticket description and selects a suitable category and subcategory.

Limitations

Manual classification takes additional time.

Similar tickets may be categorized differently by different agents.

Human errors can affect reporting and routing.

Large numbers of tickets increase repetitive work.

Classification rules are not automatically applied to every new ticket.

7. PROPOSED SYSTEM

The proposed system uses ServiceNow Flow Designer to automate incident classification. When a new incident is created, the flow is triggered and checks the ticket information.

Based on predefined conditions or keywords, the flow identifies the issue type and updates the appropriate Category and Subcategory values. The completed ticket is then available with a consistent classification.

8. SYSTEM ARCHITECTURE

The system follows a simple automation pipeline:

Incident Created

↓

Flow Designer Trigger

↓

Read Ticket Details

↓

Apply Classification Conditions

↓

Update Category / Subcategory

↓

Classified Incident

Major checkpoints:

Trigger – Detects creation of a new incident.

Data Evaluation – Reads the relevant incident fields.

Condition Check – Matches the ticket with classification rules.

Field Update – Sets Category and Subcategory automatically.

9. SYSTEM EXECUTION FLOW

Step 1 – Incident Creation: The user or support agent creates a new incident ticket.

Step 2 – Flow Trigger: The Flow Designer flow is triggered when the incident meets the configured trigger condition.

Step 3 – Ticket Evaluation: The flow reads information such as Short Description and Description.

Step 4 – Classification: The flow evaluates predefined conditions or keywords to identify

the issue type.

Step 5 – Field Update: The flow updates the Category and Subcategory fields.

Step 6 – Completion: The incident is stored with the automatically assigned classification.

10. METHODOLOGY

The project uses ServiceNow Flow Designer to implement the automation.

Trigger – Starts the flow when an incident is created.

Data – Uses incident fields such as Short Description and Description.

Conditions – Checks predefined keywords or issue patterns.

Actions – Updates Category and Subcategory values.

Testing – Creates sample incidents to verify the classification results.

Example classification rules: Hardware-related terms can be mapped to Hardware, software or access-related issues can be mapped to Software/Access, and network-related terms can be mapped to Network. The exact mappings can be adjusted according to the project's configured business rules.

11. KEY FEATURES

Automatic Classification – New incidents can be classified without manual selection.

Flow-Based Automation – The process is implemented using ServiceNow Flow Designer.

Condition-Based Rules – Classification can be performed using predefined conditions and keywords.

Automatic Field Update – Category and Subcategory are updated by the flow.

Reduced Manual Effort – Support agents spend less time on repetitive classification.

Maintainable Workflow – Rules can be modified in the flow as classification requirements change.

12. HARDWARE REQUIREMENTS

Standard computer or laptop capable of running a modern web browser.

Minimum 4 GB RAM recommended for development and testing.

Stable internet connection.

13. SOFTWARE REQUIREMENTS

ServiceNow instance / developer instance.

ServiceNow Flow Designer.

Modern web browser such as Google Chrome or Microsoft Edge.

Internet connection for accessing the ServiceNow platform.

14. SYSTEM COMPARISON

Feature	Manual Classification	Auto Ticket Classification
Classification	Performed manually	Performed automatically
Decision Logic	Agent-dependent	Flow conditions
Consistency	May vary	Standardized rules
Field Update	Manual	Automatic
Effort	Higher repetitive effort	Reduced repetitive effort
Maintenance	Depends on user practice	Rules can be updated in Flow Designer

15. ADVANTAGES

Reduces manual ticket classification.

Improves consistency in Category and Subcategory assignment.

Saves service-desk processing time.

Reduces classification errors caused by repetitive manual work.

Improves the quality of incident reporting and analysis.

Provides a centralized and maintainable automation workflow.

16. FUTURE SCOPE

The project can be enhanced with:

AI/ML-Based Classification – Use machine learning or AI to classify tickets from natural-language descriptions.

More Classification Categories – Support additional categories and subcategories.

Priority Prediction – Automatically suggest or assign priority based on ticket content.

Assignment Group Routing – Route classified incidents to the appropriate support team.

Analytics Integration – Measure classification accuracy and identify frequently occurring issues.

Continuous Rule Improvement – Update classification rules using historical incident data.

17. CONCLUSION

The Auto Ticket Classification using Flow Designer project provides a practical way to automate incident classification in ServiceNow. By evaluating ticket information and applying predefined conditions, the system can automatically update Category and Subcategory fields. This reduces repetitive manual work, improves consistency, and provides a maintainable workflow for service-desk operations. The solution can also be extended in the future with AI-based classification, automated routing, and analytics.
